EXCECUTIVE SUMMARY

Project Objective

Analyse changes in selected water-quality indicators across four River Thames stretches between 2021 and 2025, identify unusual results and assess how monitoring limitations affect interpretation.

Key Findings

1. Ammoniacal nitrogen: Overall annual concentrations were highest in 2021.
2. Anomaly: A 6.90 mg/L Cookham–Egham result increased the 2021 stretch mean from 0.095 mg/L to 0.180 mg/L, an increase of approximately 47%.
3. Orthophosphate: Overall annual averages declined through 2024 before increasing in 2025.
4. Dissolved oxygen: Annual saturation averages remained comparatively stable.

Conclusions

Water-quality conditions did not follow one consistent pattern across all indicators. Dissolved oxygen was comparatively stable, while nutrient indicators showed greater temporal and geographical variation.
The Cookham–Egham ammoniacal nitrogen result demonstrates why annual means should be reviewed alongside medians and maximums.

Recommendations

1. Continue monitoring ammoniacal nitrogen in Cookham–Egham.
2. Review high measurements alongside site, date and surrounding observations.
3. Interpret annual averages alongside sample counts and monthly coverage.
4. Maintain detection-limit flags in future analyses.

This dashboard provides descriptive screening and does not establish pollution causes or regulatory status.

WATER QUALITY TRENDS ACROSS FOUR RIVER STRETCHES

Sample Year | River Stretch | Parameter Name: Ammoniacal Nitr…(1)

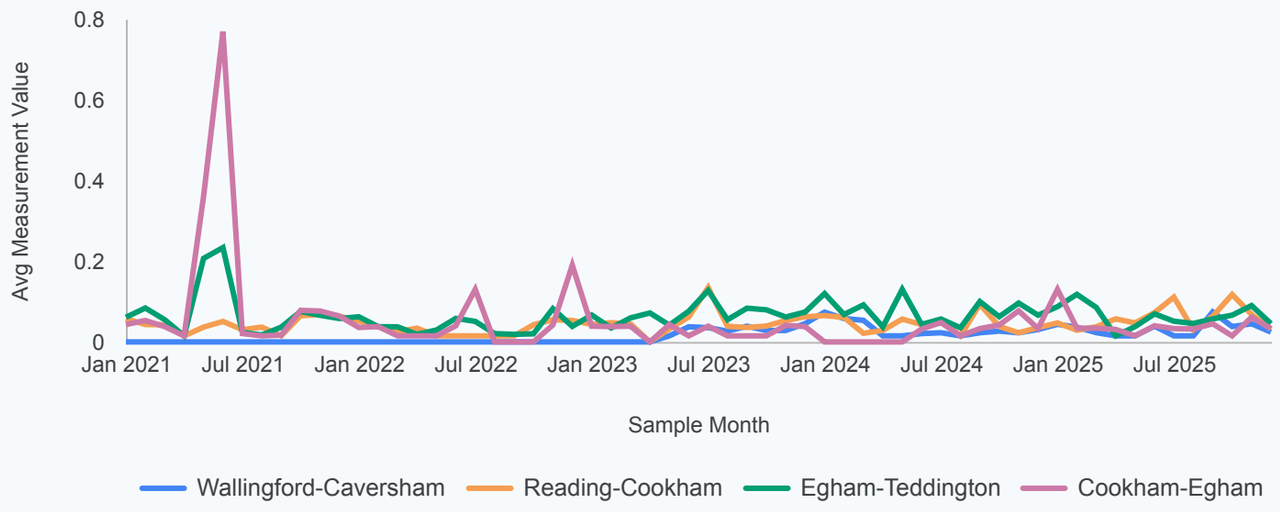

Total Samples	Months Monitored	Selected Parameters	Below Detection Limit %
850	12	1	40.71%

How To Interpret This Dashboard

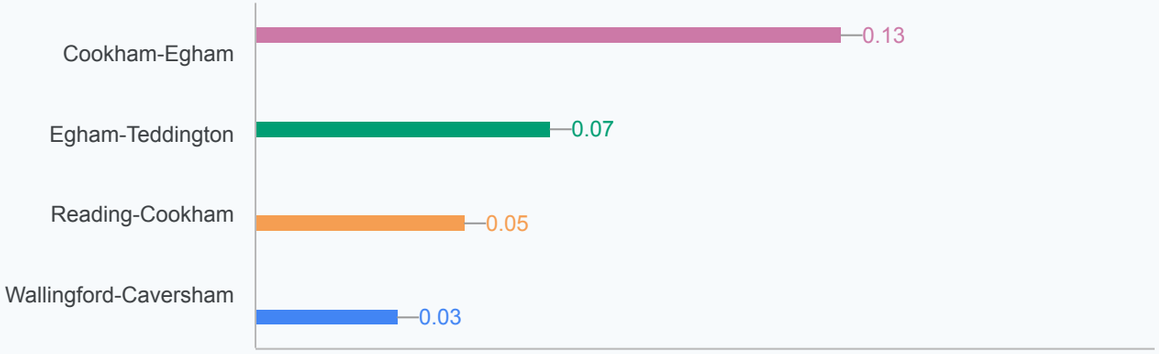

This dashboard focuses only on **four** selected parameters; pH, Ammoniacal Nitrogen as N, Orthophosphate reactive as P, and Oxygen, Dissolved, %saturation.

Select **one** parameter at a time because values with different units are not directly comparable.

Monthly Water Quality Trends By River Stretch

Average Measurement by River Stretch

Measurements Below Detection Limit by River Stretch
